

USER FLOW

Patient flow

1. Register (creates users row + patient_profiles row)
2. Add one or more pets
3. Browse the approved, online doctor directory
4. Send a chat request for a specific pet + doctor
5. Wait for doctor to accept or reject
6. If accepted → chat session begins, billing starts server-side
7. Session ends (manually or auto-ended on low balance) → wallet debited, chat history remains viewable
8. Can recharge wallet at any point before/between sessions

Doctor flow

1. Register with professional details + upload documents (photo, degree, ID proof)
2. Application sits in pending status — cannot go online or accept chats yet (T-03)
3. Admin reviews documents and approves or rejects, with a remark
4. If rejected → doctor can resubmit (goes back to pending)
5. If approved → doctor can toggle online/offline
6. While online, receives chat requests from patients
7. Accepts or rejects each request; accepted ones become active sessions
8. After each session, earnings accrue automatically from the finalized billing record
9. Can view today's/total earnings at any time

Admin flow

1. Log in (no self-registration — presumably seeded/created directly)
2. View list of pending doctor applications
3. Open an application, view protected documents, approve or reject with a remark
4. Configure platform-wide settings: rate per minute, commission %, minimum balance
5. Monitor wallet/earnings ledgers for reconciliation (T-15)
6. Review and respond to support enquiries

Fig-1: Doctor Registration

Fig-1: Chat Session

Fig-1: Billing

- **Doctor approval** — Pending is a hard gate, not just a label; nothing downstream (availability, chat) works until Approved
- **Chat/session** — the accept step is the one moment denormalized fields get written; everything else just reads them
- **Billing** — Finalized has to be idempotent (T-14), and nothing in Billing_Active pauses for network issues (T-11/T-12) since timing lives server-side
